### INTEGRATED CIRCUITS

Product specification File under Integrated Circuits, IC06 December 1990

### 74HC/HCT192

#### FEATURES

- Synchronous reversible counting
- Asynchronous parallel load
- Asynchronous reset
- Expandable without external logic
- · Output capability: standard
- I<sub>CC</sub> category: MSI

#### **GENERAL DESCRIPTION**

The 74HC/HCT192 are high-speed Si-gate CMOS devices and are pin compatible with low power Schottky TTL (LSTTL). They are specified in compliance with JEDEC standard no. 7A.

The 74HC/HCT192 are synchronous BCD up/down counters. Separate up/down clocks,  $CP_U$  and  $CP_D$  respectively, simplify operation. The outputs change state synchronously with the LOW-to-HIGH transition of either clock input. If the  $CP_U$  clock is pulsed while  $CP_D$  is held HIGH, the device will count up. If the  $CP_D$  clock is pulsed while  $CP_U$  is held HIGH, the device will count down. Only one clock input can be held HIGH at any time, or erroneous operation will result. The device can be cleared at any time by the asynchronous master reset input (MR); it may also be loaded in parallel by activating the asynchronous parallel load input ( $\overline{PL}$ ).

The "192" contains four master-slave JK flip-flops with the necessary steering logic to provide the asynchronous reset, load, and synchronous count up and count down functions.

Each flip-flop contains JK feedback from slave to master, such that a LOW-to-HIGH transition on the CP<sub>D</sub> input will decrease the count by one, while a similar transition on the CP<sub>U</sub> input will advance the count by one.

One clock should be held HIGH while counting with the other, otherwise the circuit will either count by two's or not at all, depending on the state of the first flip-flop, which cannot toggle as long as either clock input is LOW. Applications requiring reversible operation must make the reversing decision while the activating clock is HIGH to avoid erroneous counts.

The terminal count up  $(\overline{TC}_U)$  and terminal count down  $(\overline{TC}_D)$  outputs are normally HIGH. When the circuit has reached the maximum count state of 9, the next HIGH-to-LOW transition of CP<sub>U</sub> will cause  $\overline{TC}_U$  to go LOW.  $\overline{TC}_U$  will stay LOW until CP<sub>U</sub> goes HIGH again, duplicating the count up clock.

Likewise, the  $\overline{TC}_D$  output will go LOW when the circuit is in the zero state and the CP<sub>D</sub> goes LOW. The terminal count outputs can be used as the clock input signals to the next higher order circuit in a multistage counter, since they duplicate the clock waveforms. Multistage counters will not be fully synchronous, since there is a slight delay time difference added for each stage that is added.

The counter may be preset by the asynchronous parallel load capability of the circuit. Information present on the parallel data inputs ( $D_0$  to  $D_3$ ) is loaded into the counter and appears on the outputs ( $Q_0$  to  $Q_3$ ) regardless of the conditions of the clock inputs when the parallel load ( $\overline{PL}$ ) input is LOW. A HIGH level on the master reset (MR) input will disable the parallel load gates, override both clock inputs and set all outputs ( $Q_0$  to  $Q_3$ ) LOW. If one of the clock inputs is LOW during and after a reset or load operation, the next LOW-to-HIGH transition of that clock will be interpreted as a legitimate signal and will be counted.

### 74HC/HCT192

#### QUICK REFERENCE DATA

GND = 0 V;  $T_{amb}$  = 25 °C;  $t_r$  =  $t_f$  = 6 ns

| SYMBOL                              | PARAMETER                                  | CONDITIONS                                     | TYP |     |      |

|                                     | FARAMETER                                  | CONDITIONS                                     | HC  | нст | UNIT |
| t <sub>PHL</sub> / t <sub>PLH</sub> | propagation delay $CP_D$ , $CP_U$ to $Q_n$ | C <sub>L</sub> = 15 pF; V <sub>CC</sub> = 5 V  | 20  | 20  | ns   |
| f <sub>max</sub>                    | maximum clock frequency                    | $C_{L} = 15  \text{pr},  v_{CC} = 5  \text{v}$ | 40  | 45  | MHz  |
| CI                                  | input capacitance                          |  | 3.5 | 3.5 | pF   |
| C <sub>PD</sub>                     | power dissipation capacitance per package  | notes 1 and 2                                  | 24  | 28  | pF   |

#### Notes

1. C<sub>PD</sub> is used to determine the dynamic power dissipation (P<sub>D</sub> in  $\mu$ W):

 $P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o)$  where:

 $f_i$  = input frequency in MHz  $f_o$  = output frequency in MHz

 $\Sigma (C_L \times V_{CC}^2 \times f_o) = sum of outputs$ 

 $C_L$  = output load capacitance in pF

 $V_{CC}$  = supply voltage in V

2. For HC the condition is  $V_I = GND$  to  $V_{CC}$ For HCT the condition is  $V_I = GND$  to  $V_{CC} -1.5$  V

### 74HC/HCT192

#### DC CHARACTERISTICS FOR 74HCT

For the DC characteristics see "74HC/HCT/HCU/HCMOS Logic Family Specifications".

Output capability: standard  $I_{CC}$  category: MSI

#### Note to HCT types

The value of additional quiescent supply current ( $\Delta I_{CC}$ ) for a unit load of 1 is given in the family specifications. To determine  $\Delta I_{CC}$  per input, multiply this value by the unit load coefficient shown in the table below.

| INPUT                        | UNIT LOAD COEFFICIENT |
|------------------------------|-----------------------|
| D <sub>n</sub>               | 0.35                  |
| <u>CP</u> U, CP <sub>D</sub> | 1.40                  |
| PL                           | 0.65                  |
| MR                           | 1.05                  |
